interfaces and layered systems “new physics” and “spintronics”?

general idea: the close contact of materials with different (alternative) properties might lead to **new phenomena**

e.g. – interface of SrTiO₃/LaTiO₃ (insulators) is metallic

a multilayer **reduces the dimension and forces the interaction**
coupling phenomena might show up

e.g. – RKKY-interaction
– colossal magnetoresistance
– changed characteristic temperatures

present case: multilayers of a FM with a HTSC (both metals) seem to show an metal/insulator transition in ellipsometry transition for small periods — but stay superconducting / magnetic

so: **what happens with the magnetisation and the superconduction order parameter?**

essence

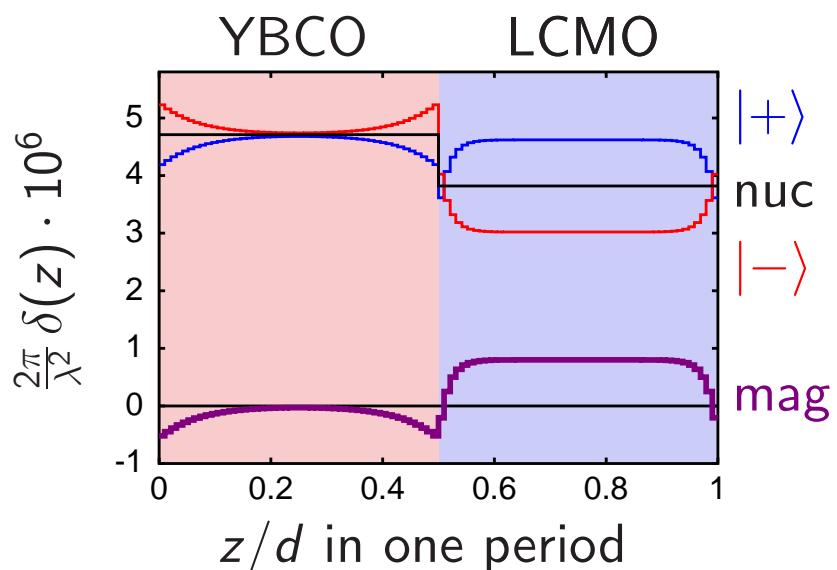

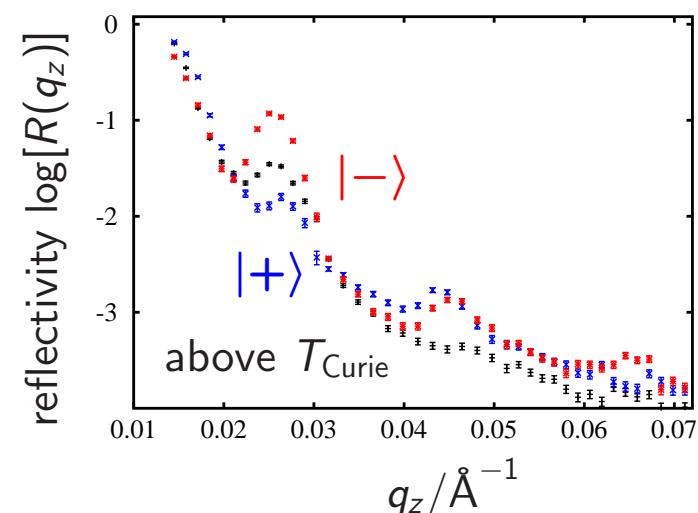

question: What is the magnetic induction (profile) in HTSC / FM multilayers?

method: polarised neutron reflectometry allows for the determination of $\rho(z)$ and $B_{\parallel}(z)$

answers: FM layers magnetised parallel

net magnetic moment in SC at the interfaces, antiparallel to FM magnetisation

SC creates and aligns domain walls in FM

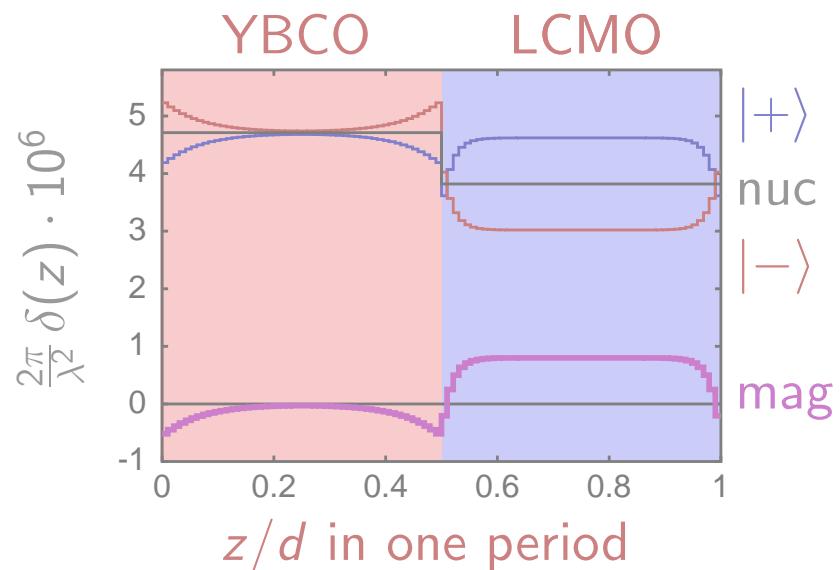

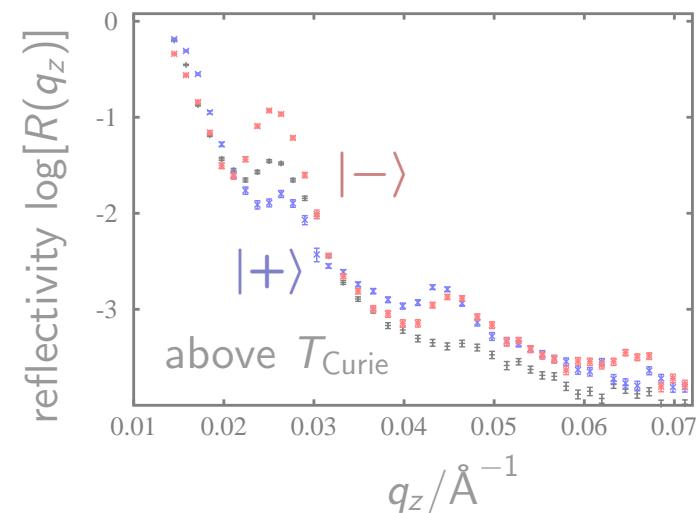

overview

question: What is the magnetic induction (profile) in HTSC / FM multilayers?

method: polarised neutron reflectometry allows for the determination of $\rho(z)$ and $\mathbf{B}_{\parallel}(z)$

answers: FM layers magnetised parallel net magnetic moment in SC at the interfaces, antiparallel to FM magnetisation
SC creates and aligns domain walls in FM

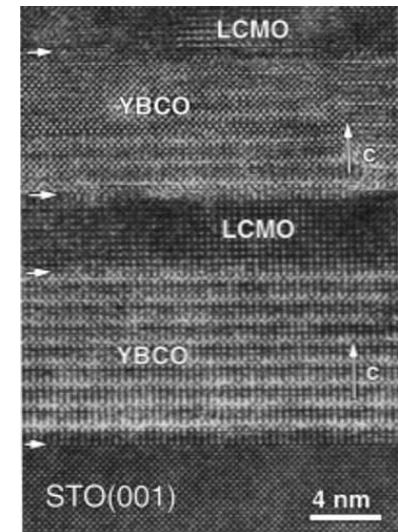

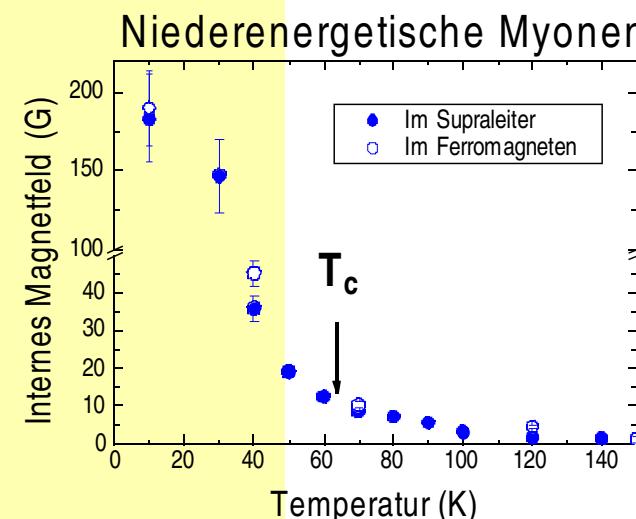

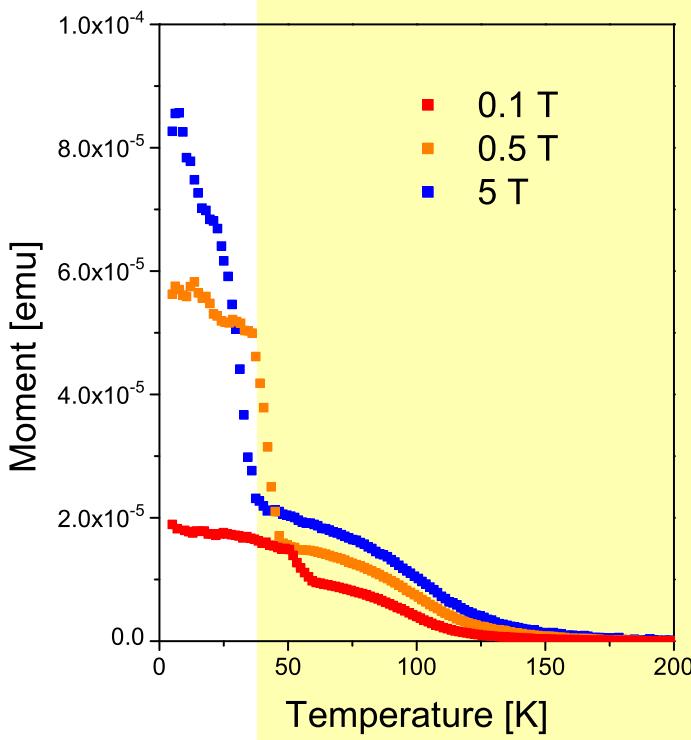

motivation / history:

observation of coexistence of FM and SC in
RuSrCuGdO multilayers:

enhanced magnetism below T_c

(spring 2003, μ SR and magnetisation
measurements at PSI)

→ competitive order parameters

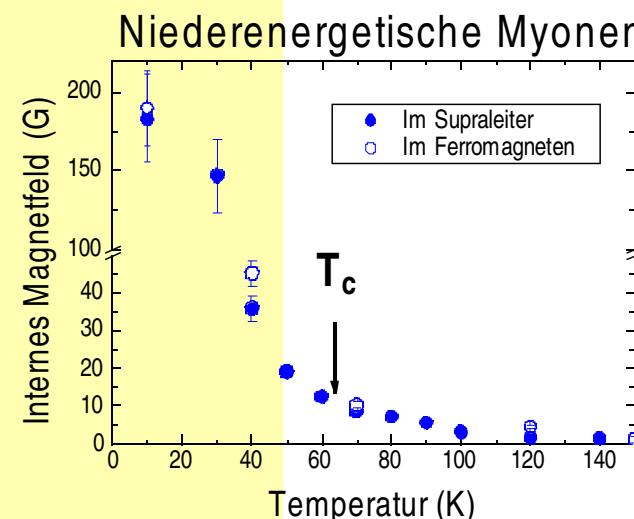

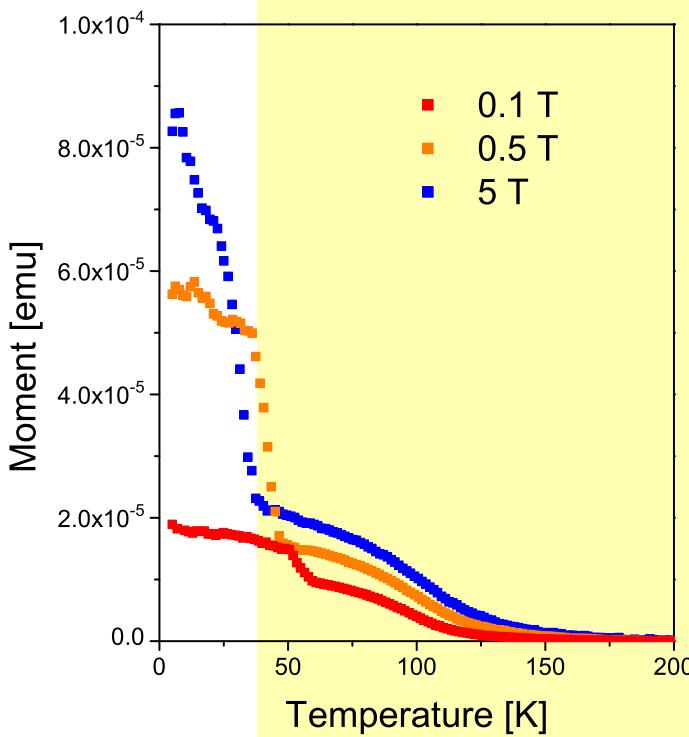

questions:

- interaction of FM and SC at the interfaces?
- location of the magnetisation?
- coupling through the layer?

motivation / history:

observation of coexistence of FM and SC in
RuSrCuGdO multilayers:
enhanced magnetism below T_c

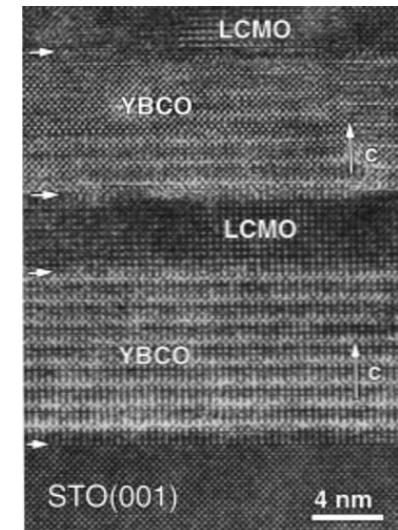

(spring 2003, μ SR and magnetisation
measurements at PSI)

method of choice
(for a neutron scatterer):

neutrons!

in particular *polarised n-reflectometry*

overview

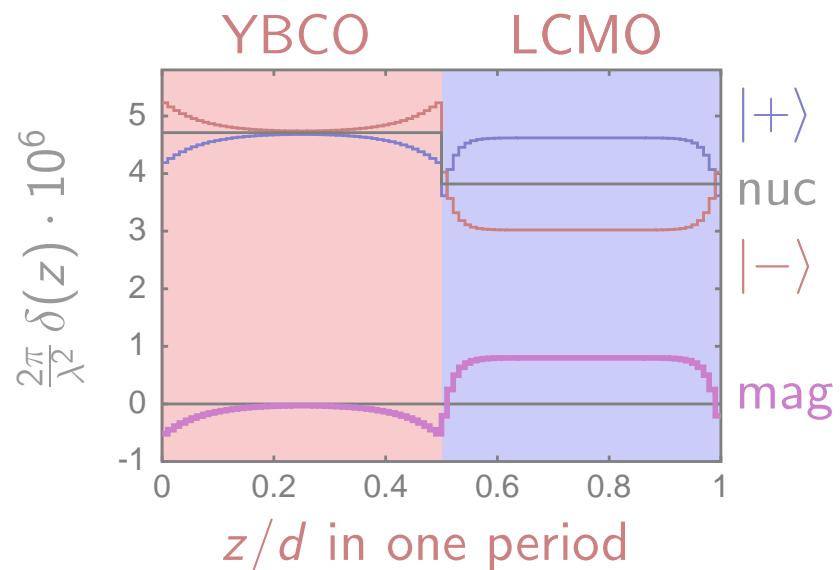

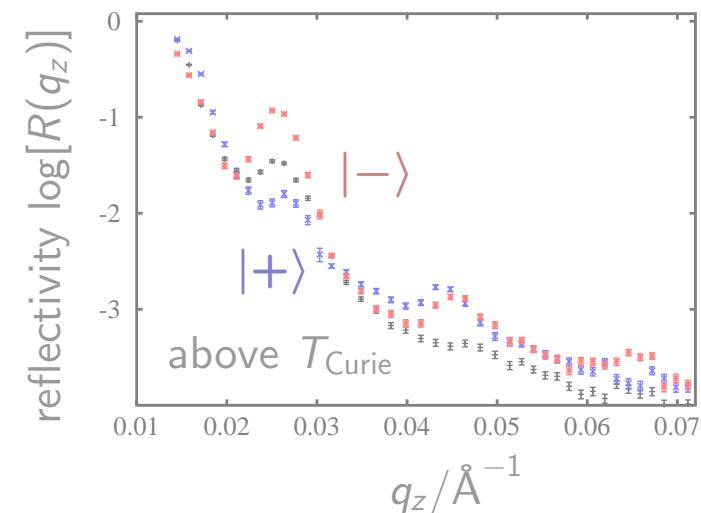

question: What is the magnetic induction (profile) in HTSC / FM multilayers?

method: polarised neutron reflectometry allows for the determination of $\rho(z)$ and $B_{\parallel}(z)$

answers: FM layers magnetised parallel

net magnetic moment in SC at the interfaces, antiparallel to FM magnetisation

SC creates and aligns domain walls in FM

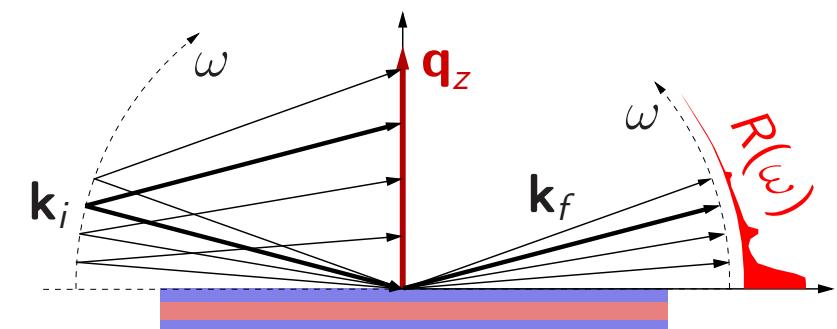

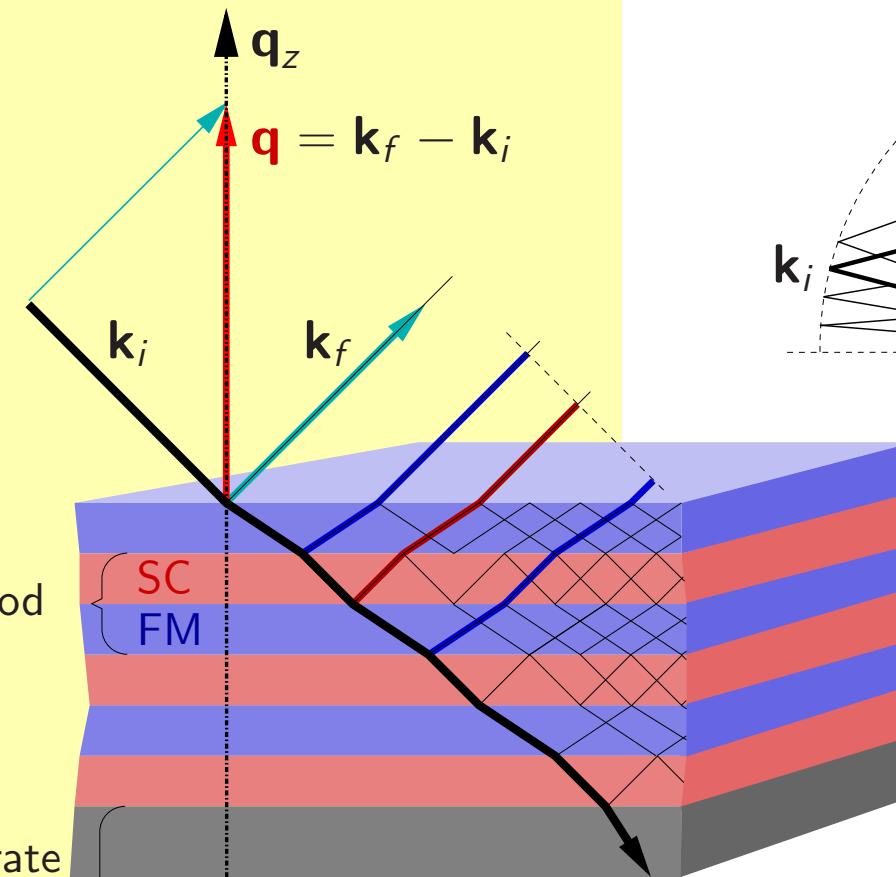

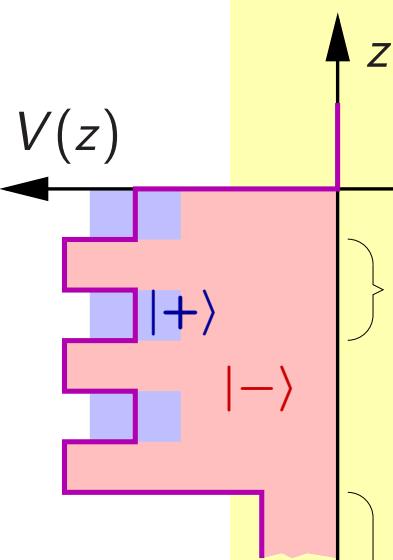

reflectometry

interference of beams reflected from parallel interfaces

periodic structure \Rightarrow Bragg-condition for constructive interference

scattering potential:

$$\begin{aligned} V &= V_{\text{nuc}} \pm V_{\text{mag}} \\ &= V_{\text{nuc}} + \mu \mathbf{B}_{\parallel} \end{aligned}$$

layer thickness ratio 1:1
 \Rightarrow extinction of even Bragg-peaks

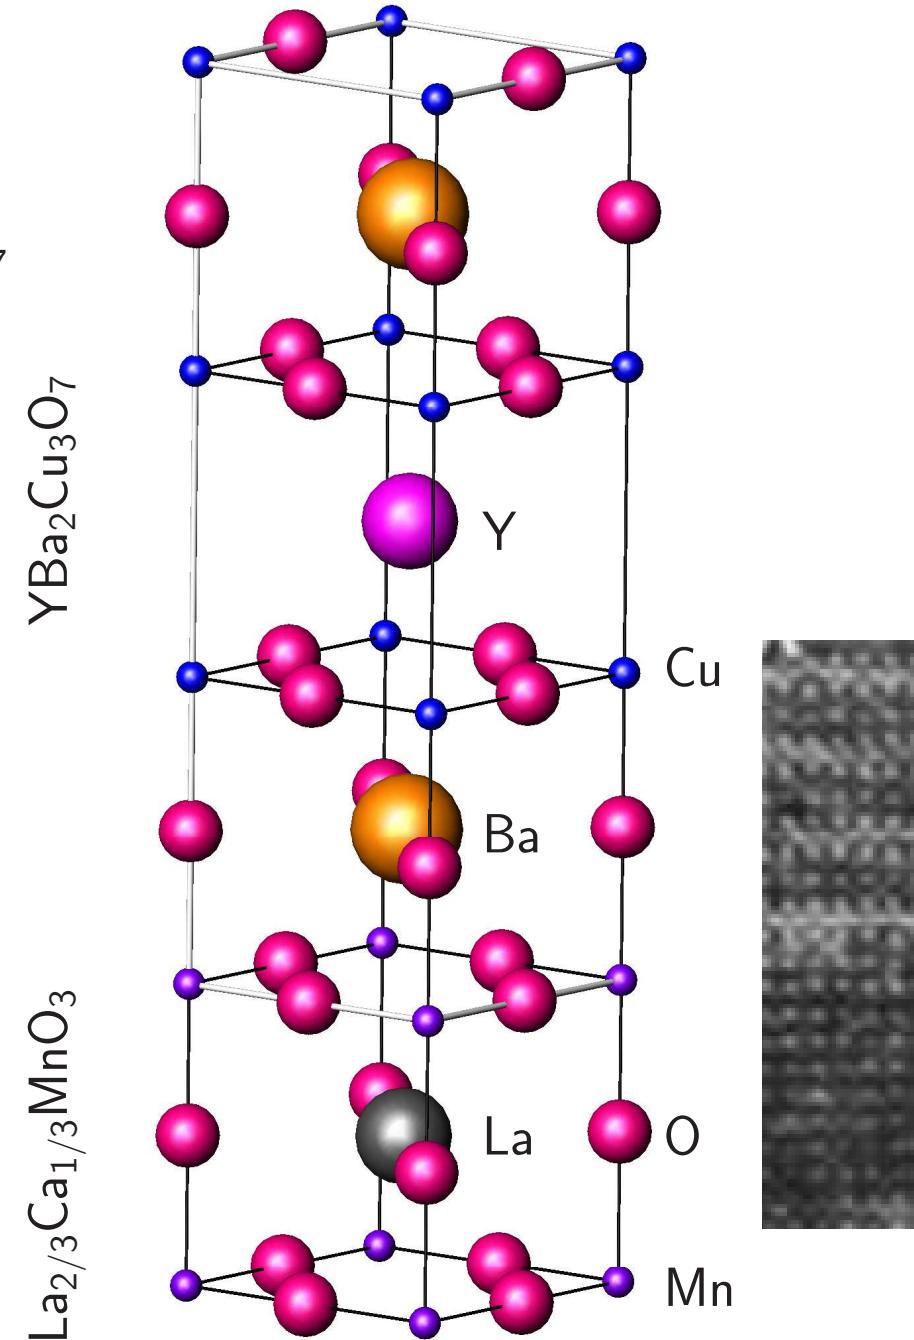

reflectometry tailored samples

materials: HTSC YBCO $\text{YBa}_2\text{Cu}_3\text{O}_7$
 YPBCO $\text{Y}_{0.6}\text{Pr}_{0.4}\text{Ba}_2\text{Cu}_3\text{O}_7$
 FM LCMO $\text{La}_{2/3}\text{Ca}_{1/3}\text{MnO}_3$
 substr. STO SrTiO_4
 size: $10 \times 10 \text{ mm}^2$, $5 \times 5 \text{ mm}^2$

produced: by *Pulsed Laser Deposition*

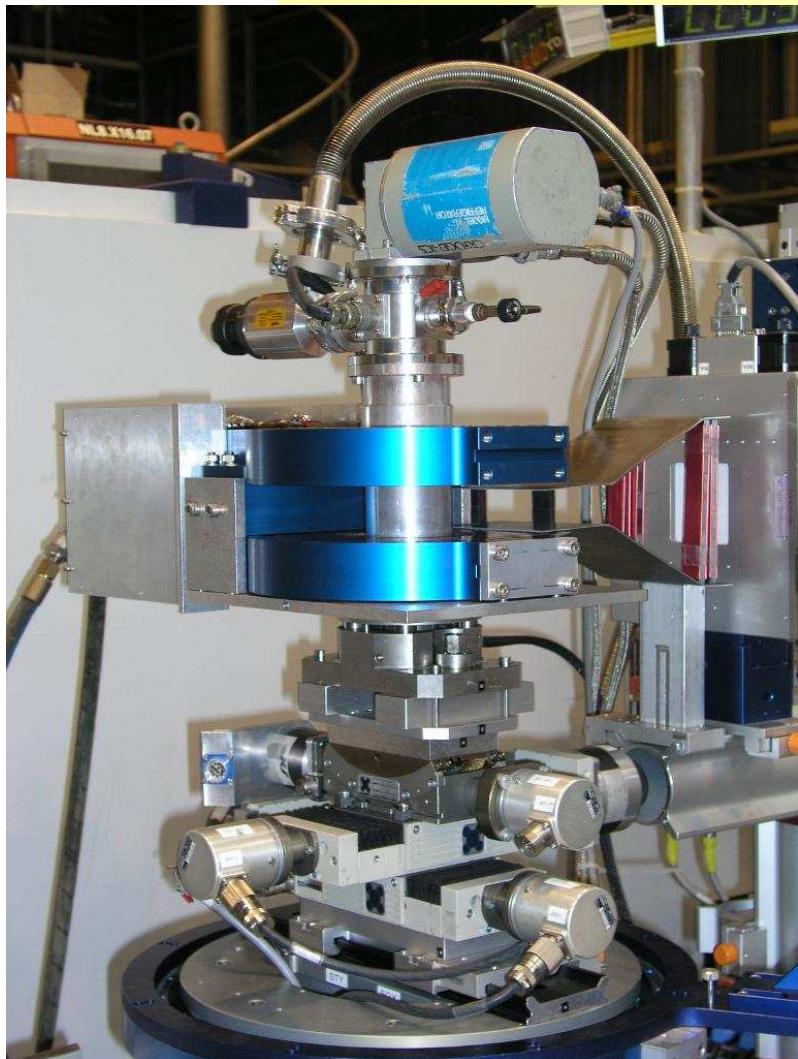

period: 200 \AA to 500 \AA
 5 to 16 periods

ratios: 1 : 1 and 1 : 2
 to cause extinction

reflectometry

sample environment (at SINQ):

sample holder

closed cycle refrigerator
 $8 \text{ K} < T < 300 \text{ K}$

Helmholtz coils
 $H \leq 1000 \text{ Oe}$
vol: $40 \times 40 \times 40 \text{ mm}^3$

translation stages for alignment

ω -rotation stage

instruments: Morpheus & ANOR, SINQ;
ADAM, ILL; and HADAS, FZ Jülich

reflectometry

$H = 100$ Oe

field cooled

$T = 10, 300$ K

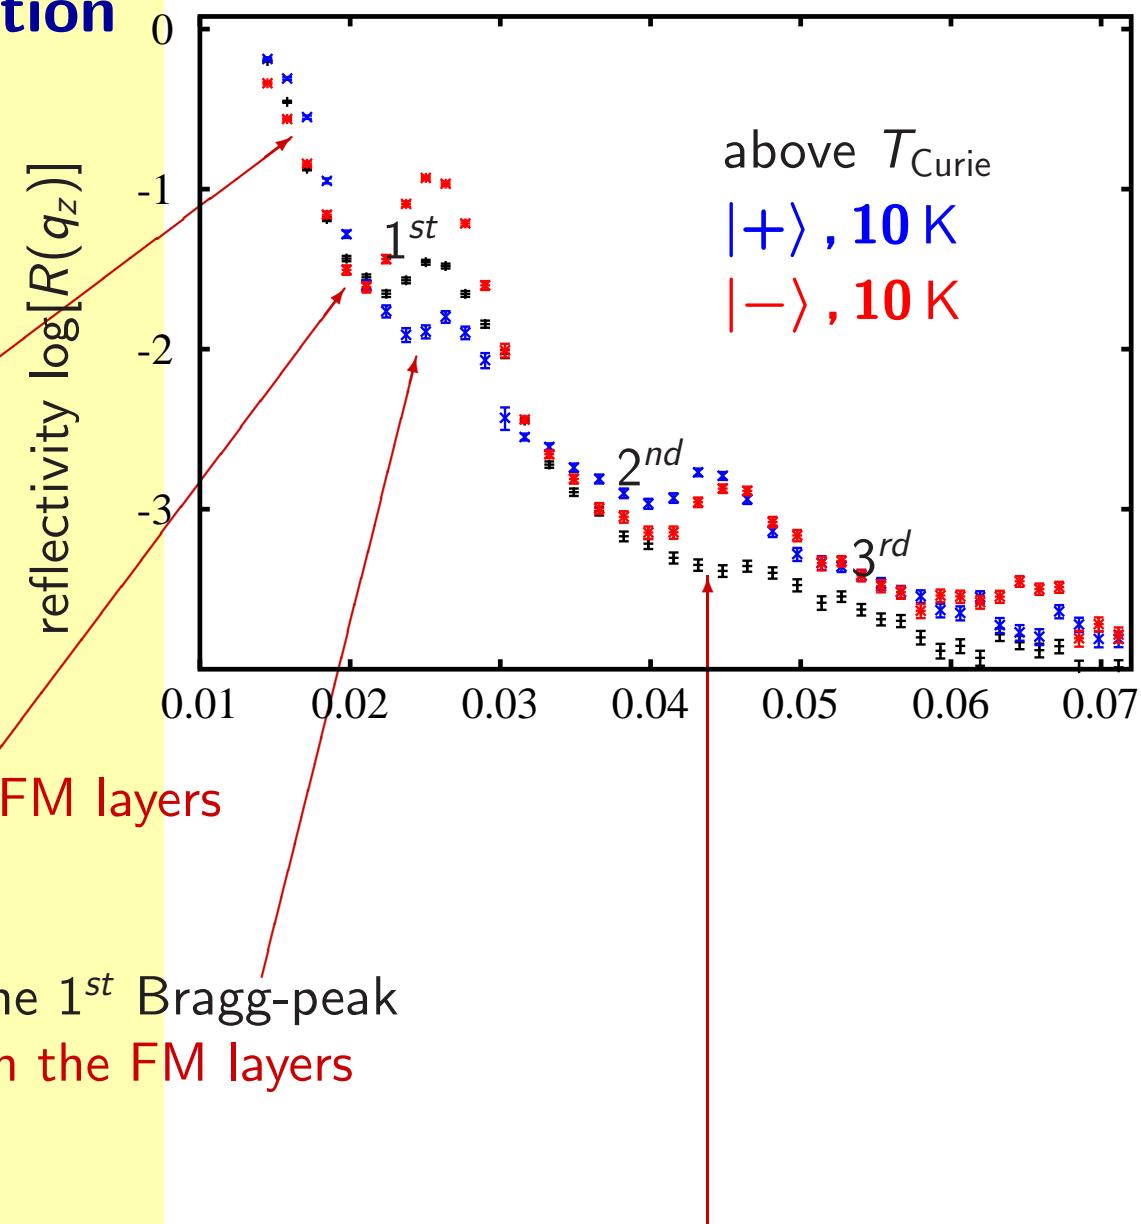

direct interpretation

splitting of the edge of total reflection
 \Rightarrow changed potential of the surface

no half-order Bragg-peak
 \Rightarrow parallel alignment of **B** in the FM layers

intensity variation of the 1st Bragg-peak
 \Rightarrow changed potential in the FM layers
 B_{\parallel} can be determined

appearance of a 2nd order Bragg-peak
 $\Rightarrow B_{\parallel}(z)$ and $V_{\text{nuc}}(z)$ have different symmetry

reflectometry simulations

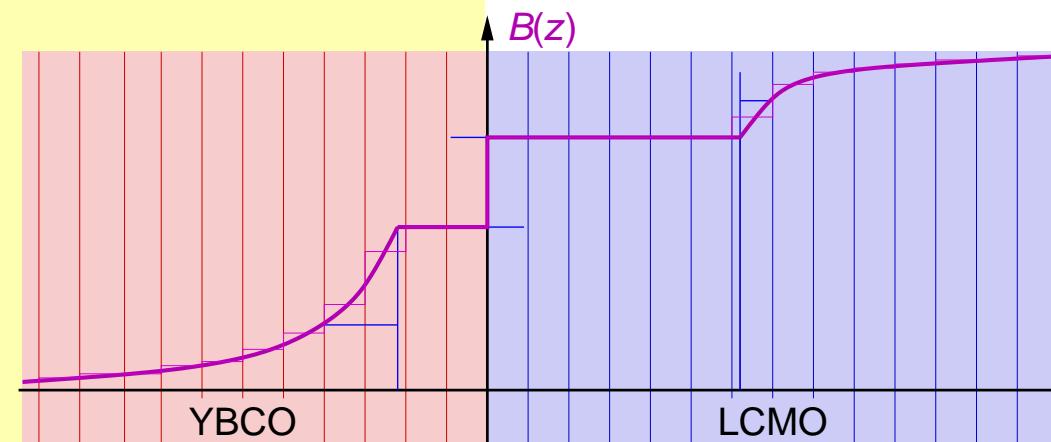

simulations performed with EDXR by Petr Mikulík (no fitting)

bilayer structure has been broken down to some 100 sublayers to pay respect to $\mathbf{B}(z)$.

analytic expressions for $B(z)$:

cosh-functions

off-sets with constant B

decrease of layer thickness towards the borders taken into account

reflectometry simulations

PNR at RT and below T_{Curie} and T_c
exclude all models besides

AFM-region within LCMO

charge-injection from YBCO leads to
a doping of LCMO and thus to an
AFM ground state

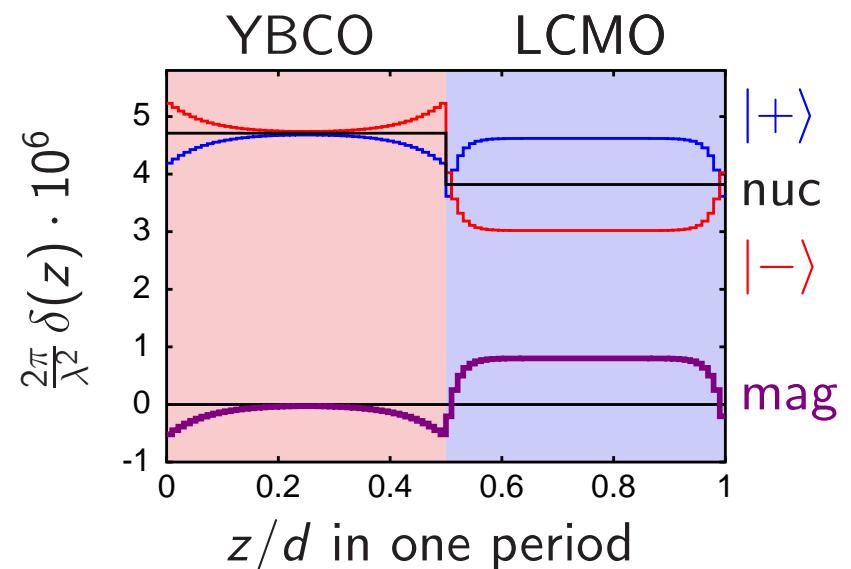

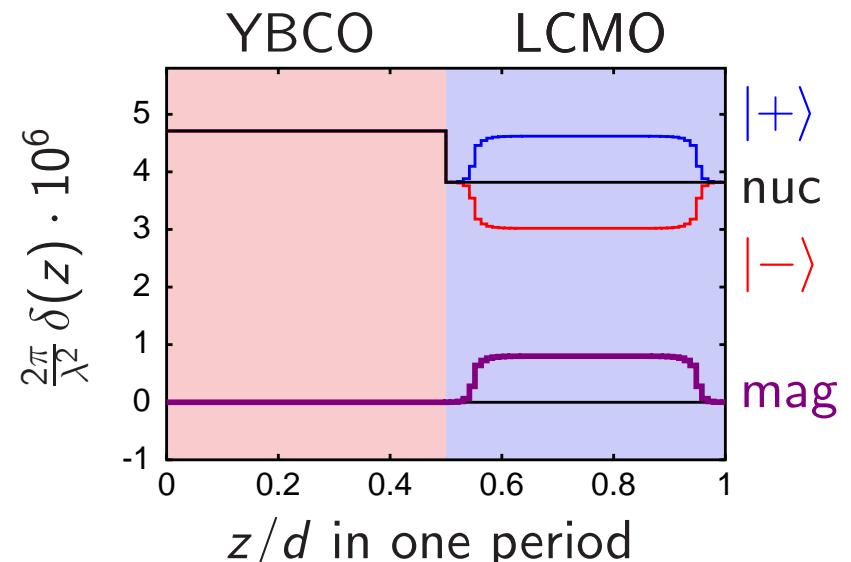

antiphase magnetic proximity effect

AF coupling of Mn and Cu moments
through oxygen

or

Cooper pairs penetrate into LCMO
and are *polarised*

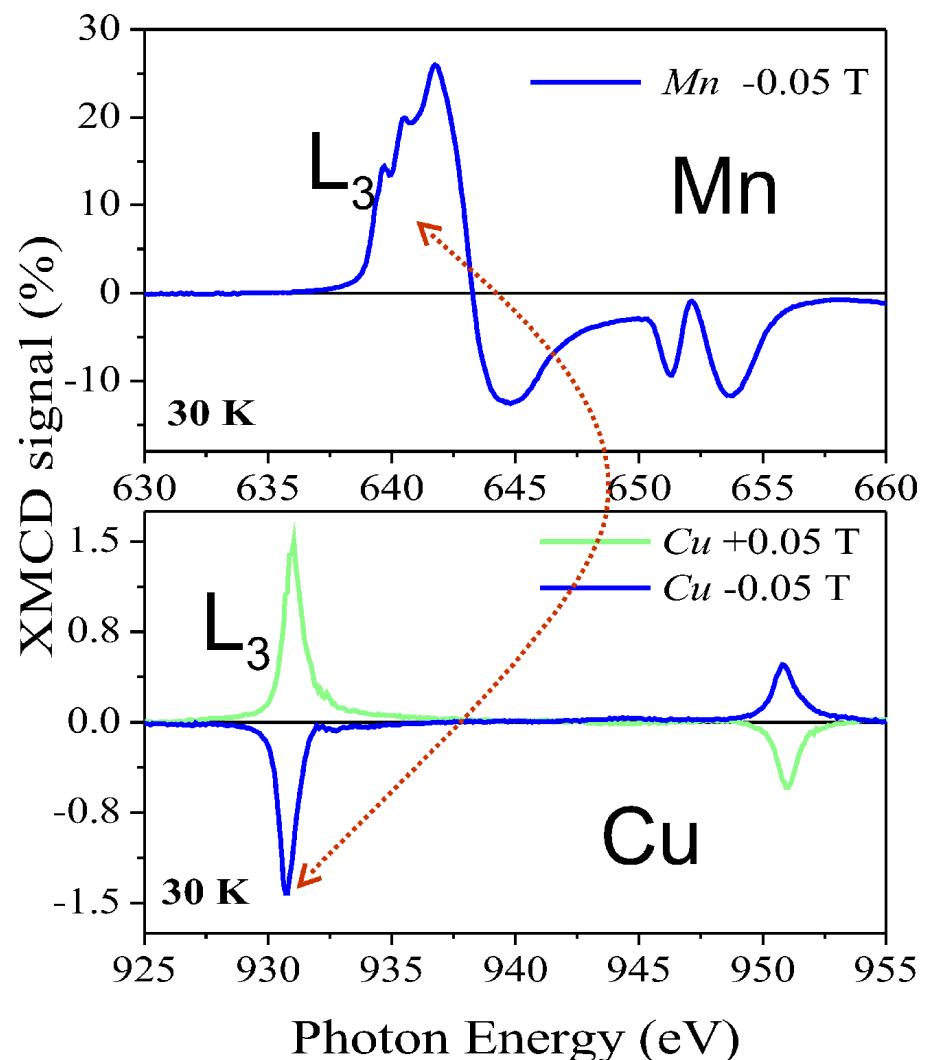

⇒ antiparallel magnetisation in YBCO

X-ray magnetic circular dichroism:

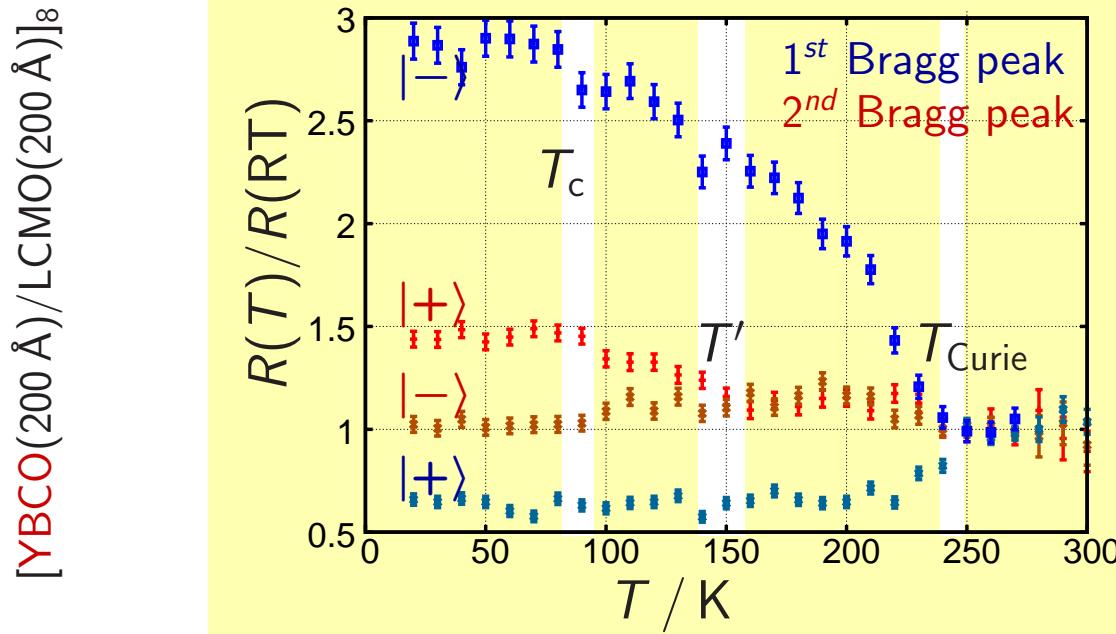

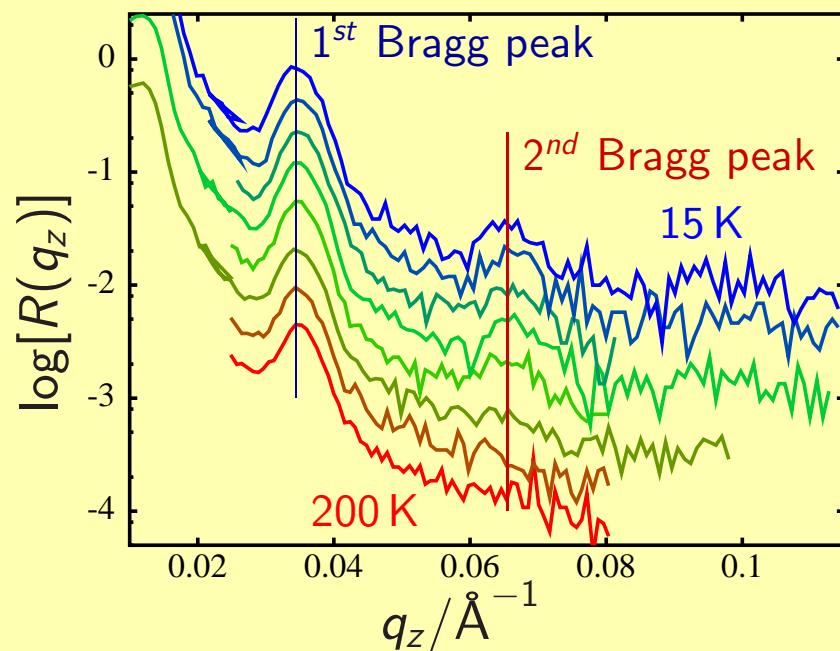

measurements by J. Chakhalian and
B. Keimer, Stuttgart
performed at APS, Chicago.

- magnetic moment on Cu detected
 - it is **antiparallel** to the moment on Mn
- ⇒ antiphase proximity effect is strongly supported!

graph taken from a talk by J. Chakhalian given at the Summer School on Interfaces of Oxides, Stuttgart, July 2005

T dependence of $R(q_z)$

T_{Curie} ($160 \rightarrow 270 \text{ K}$)

onset of FM: changed contrast

T' ($\approx 140 \text{ K}$)

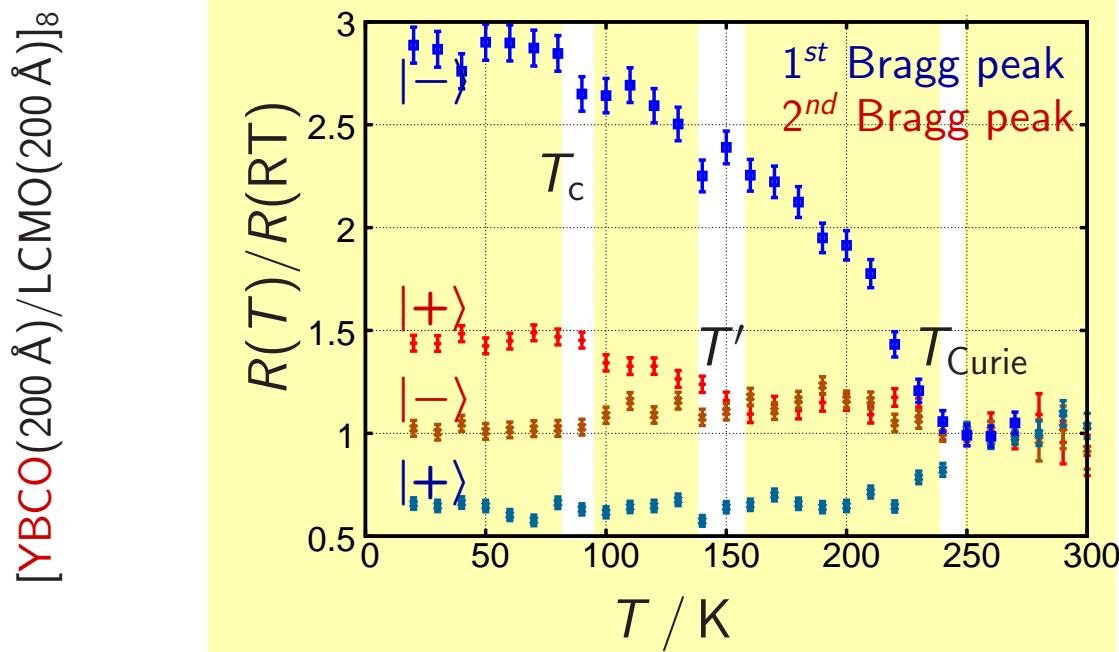

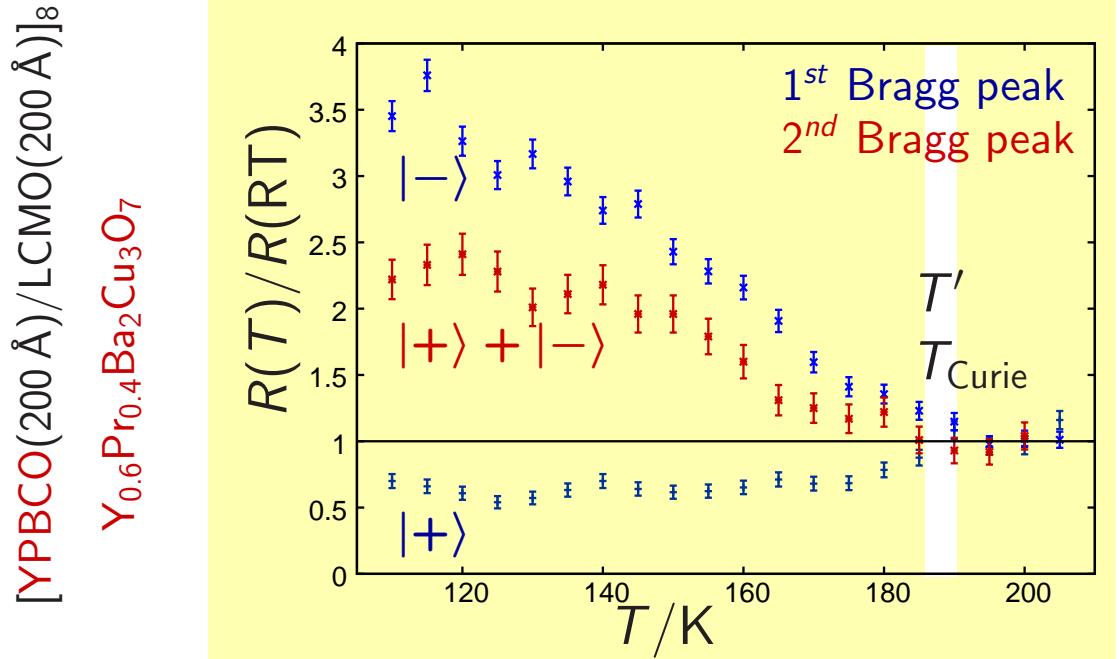

formation of 2^{nd} peaks

$B(z)$ and $V_{\text{nuc}}(z)$ differ

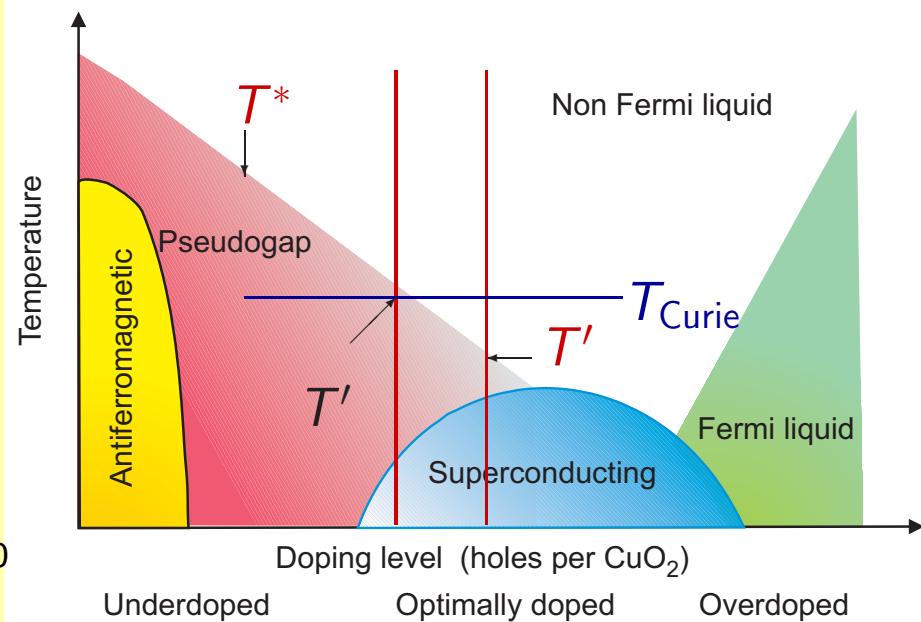

T_c ($60 \rightarrow 90 \text{ K}$)

onset of SC

T dependence of $R(q_z)$

$T' \approx T^*$ varies with doping!

overview

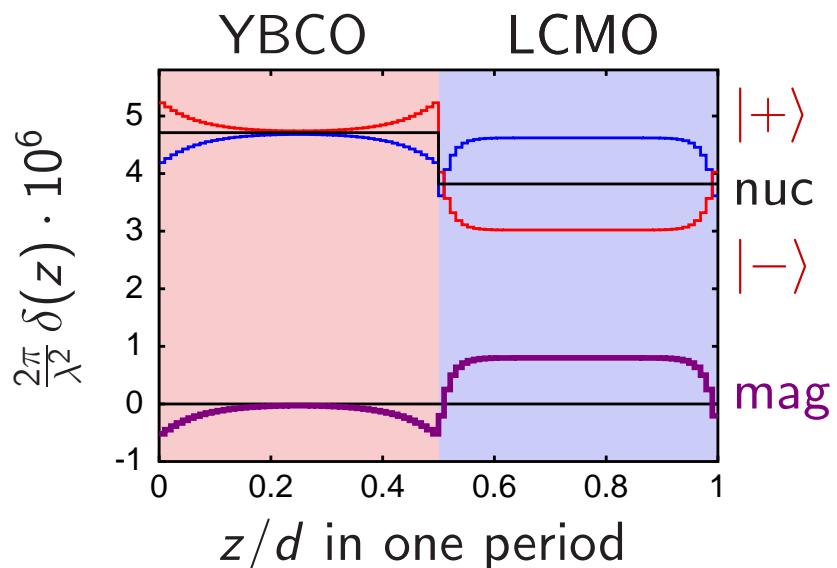

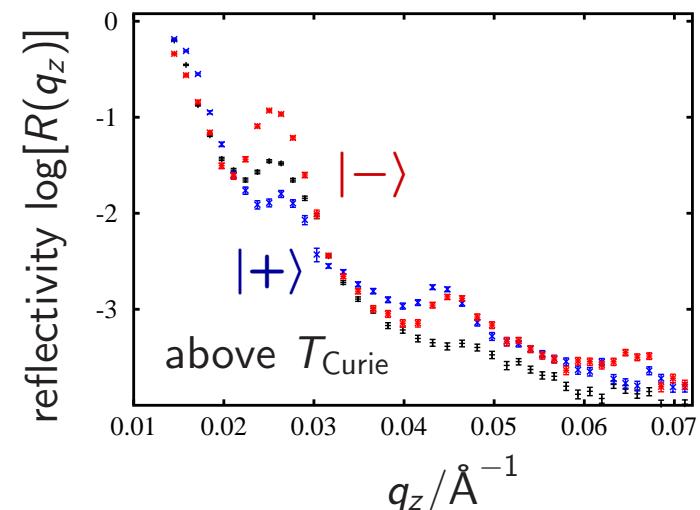

question: What is the magnetic induction (profile) in HTSC / FM multilayers?

method: polarised neutron reflectometry allows for the determination of $\rho(z)$ and $B_{\parallel}(z)$

answers: FM layers magnetised parallel

net magnetic moment in SC at the interfaces, antiparallel to FM magnetisation

SC creates and aligns domain walls in FM

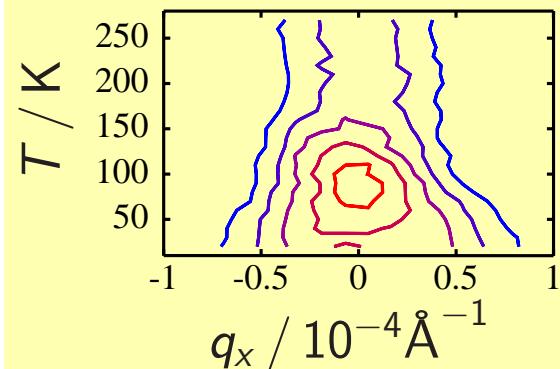

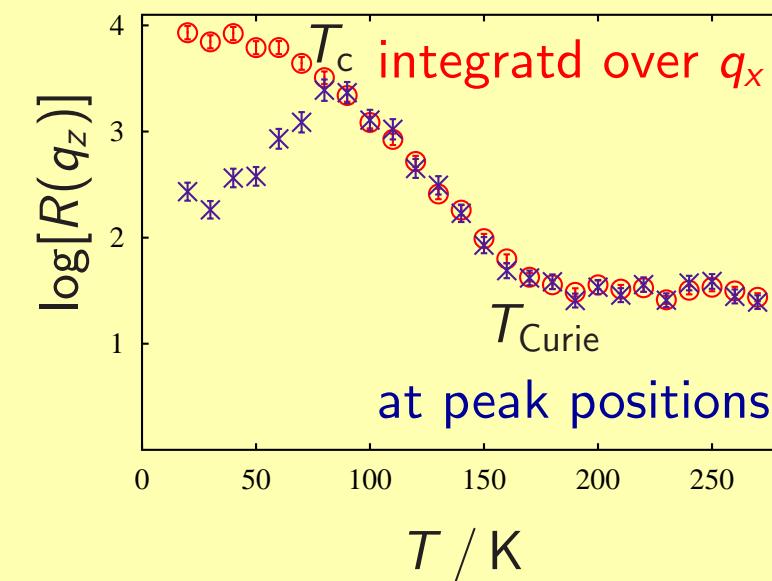

off-specular scattering

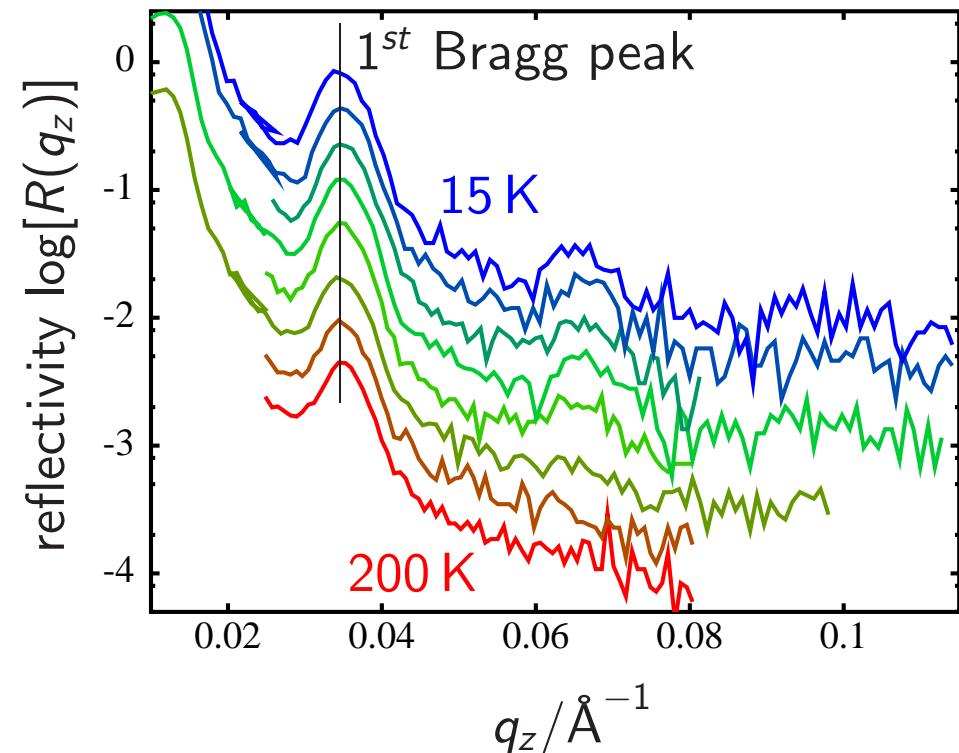

ω -scans

non-polarised, various T

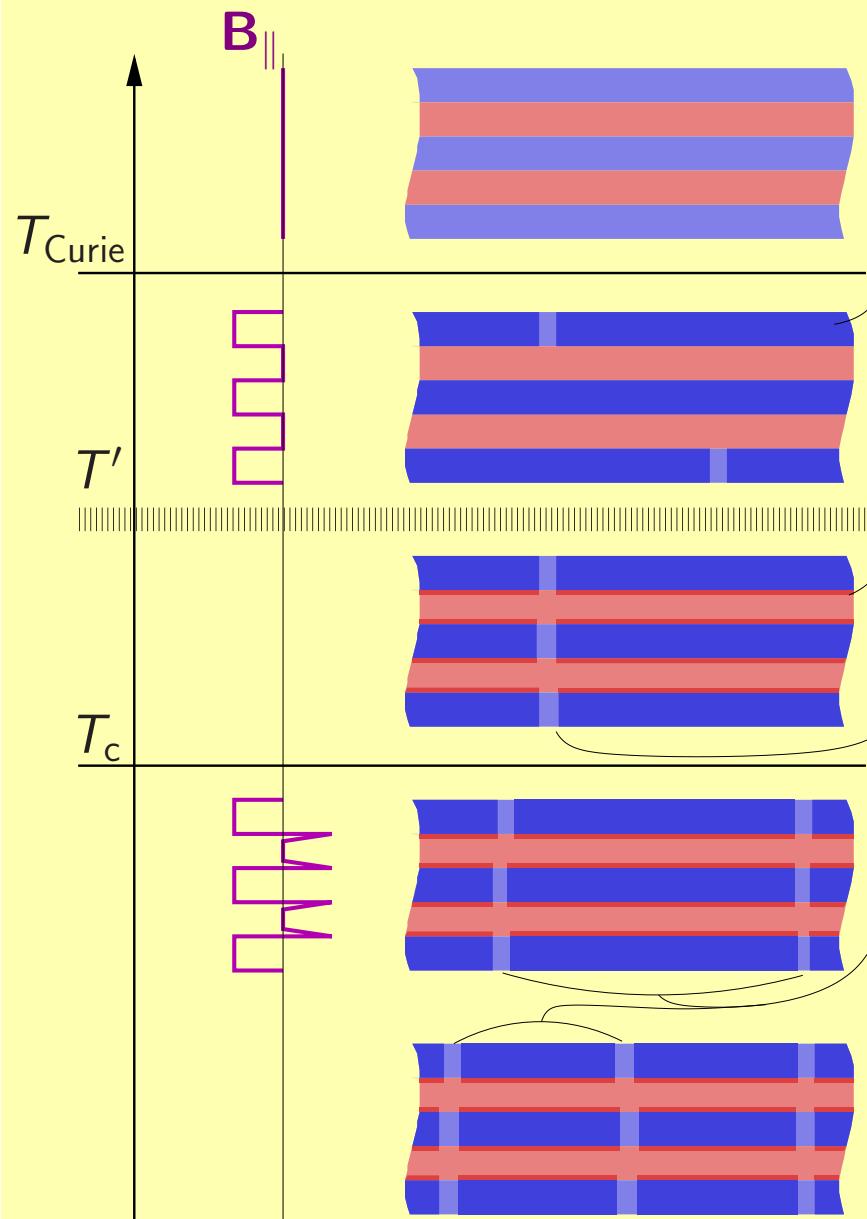

sample: [YBCO(100 Å)/LCMO(100 Å)]₇

magnetic domains shrink below T_c
from $10 \mu\text{m}$ to $5 \mu\text{m}$ when cooling

conclusion:

- all LCMO layers are magnetised parallel
- interface effect of $\mathbf{B}(z)$ of the order of 10 \AA is measured at $T_c < T' \approx 140 \text{ K} < T_{\text{Curie}}$
- *magnetic dead layer or antiphase proximity effect*
- simultaneous appearance of Bragg-sheets
- *vertical correlation of magnetic domains*
- increase of off-specular scattering below T_c
- shrinking of magnetic domains / characteristic lengthscale
- correlation of domain size with $T < T_c$ and XMCD measurements support the *antiphase proximity effect*

essence
