## Abstract:

The proposed Mu3e experiment will study the lepton flavor violating decay  $\mu \rightarrow eee$  which is strongly ( $10^{-50}$ ) suppressed in the standard model, but enhanced to observable levels in many models for new physics. In order to achieve the proposed branching ratio

sensitivity of  $10^{-16}$  the detector has to have a high rate capability and a good background suppression, which in turn requires excellent momentum and vertex resolution. The Mu3e detector consists of two double layers of high voltage monolithic active pixel sensors (HV-MAPS) around a target double cone. To minimize

multiple scattering of the low energetic decay electrons ( $< 53$  MeV), an ultra-light design is proposed, using HV-MAPS thinned to  $\leq 50 \mu\text{m}$ . With on-sensor pre-amplification, discrimination and zero-suppression, a separate read-out chip can be omitted, which further reduces the material budget.

## Theory:

In the Standard Model (SM) of elementary particle physics, the decay  $\mu \rightarrow eee$  can occur via lepton mixing. It is however suppressed to an unobservable low branching fraction of  $O(10^{-50})$ . Any observation of  $\mu \rightarrow eee$  would be a clear signal for new physics, and many models predict enhanced lepton flavor violation, e.g. super-symmetry, grand unified models, left-right symmetric models, models with an extended Higgs sector, large extra dimensions etc. LFV can proceed either via loops or at tree level. Introducing a common scale  $\Lambda$  and a relative strength  $\kappa$  between the dipole term and the 4-fermion contact interaction gives a simplified Lagrangian:

$$L_{LFV} = \frac{m_\mu}{(\kappa+1)\Lambda^2} A_R \bar{\mu}_R \sigma^{\mu\nu} e_L F_{\mu\nu} + \frac{\kappa}{(\kappa+1)\Lambda^2} (\bar{\mu}_L \gamma^\mu e_L)(\bar{e}_L \gamma^\mu e_L)$$

The main sources of background are accidental coincidences of tracks from Michel decays with electron-positron pairs from Bhabha scattering, photon conversion etc. and the radiative decay with internal conversion  $\mu \rightarrow eee\nu$  (BR  $3.4 \times 10^{-5}$ ). The first requires excellent vertex and timing resolution, the second the best possible momentum resolution.

## Muon beam at PSI:

Paul Scherrer Institute Switzerland:

- 2.2 mA of 590 MeV/c protons
- Future: up to 3 mA (1.8 MW)
- Phase I:
  - Surface muons from target E
  - Up to a few  $10^8 \mu/s$
- Phase II:
  - New beam line at the neutron source
  - Several  $10^9 \mu/s$  possible

## Outlook:

- 2012 Letter of intent to PSI, Tracker prototype, technical design
- 2013 Technical design report, detector construction
- 2014 Installation and commissioning at PSI
- 2015 Data taking at up to a few  $10^8 \mu/s$
- 2016+ Construction of new beam-line at PSI
- 2017++ Data taking at up to  $3 \cdot 10^9 \mu/s$

## Challenges:

- High rates
- Excellent momentum resolution
- Good vertex resolution
- Good timing resolution
- Extremely low material budget

## Tracking:

Use central part of the detector for track finding, vertexing and timing. The best resolution in presence of multiple scattering is obtained from tracks curling half turns in the  $B \sim 1$  T field. Momentum resolutions  $< 0.3$  MeV/c are possible over a wide kinematic range, making a three track mass resolution of  $\sim 0.5$  MeV/c<sup>2</sup> possible.

## Detector Concept:

### Long Tube Design:

For a high acceptance of recurling particles, the detector needs to be long ( $> 1$  m). However, only the central  $\sim 25$  cm needs to be thin, simplifying mechanics and allowing for precise timing in thick scintillator tiles.

### Target:

Double cone target made from  $70 \mu\text{m}$  Aluminum – large area for good vertex separation.

### Mechanics:

Sensors supported on  $25 \mu\text{m}$  Kapton™ strips with signal and power traces printed in Aluminum – extremely light and surprisingly sturdy.

### Timing:

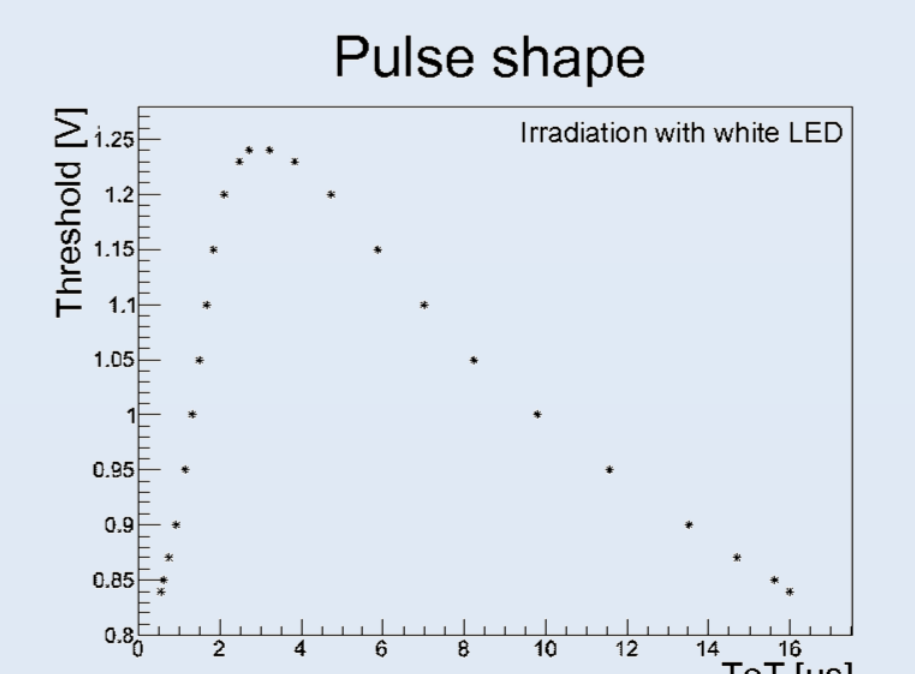

$250 \mu\text{m}$  scintillating fibers in the central region for first timing measurement. Precise timing from  $\sim 1$  cm thick scintillating tiles in the recurl tubes

### Pixel Sensor:

- $80 \times 80 \mu\text{m}^2$  pixels sensors cut to  $2 \times 6$  or  $1 \times 6$  cm<sup>2</sup>
- Thinned to  $\leq 50 \mu\text{m}$   
→ thickness of 4 pixel layers  $\sim 2 \%$   $X_0$
- Total  $\sim 200$  Million pixels
- Cooled by helium atmosphere
- Maximum readout frequency  $\sim 20$  MHz
- Binary readout

### Readout:

- Triggerless readout with  $\sim 100$  Gbyte/s to an online farm.
- Fast track finding and reconstruction on GPUs ( $> 10^9$  tracks/s).
- Reduction to  $\sim 100$  Mbyte/s for online storage and analysis.

## HV-MAPS:

Using a commercial 180 nm CMOS process originating in the automotive industry, high voltage monolithic active pixel sensors housing the pixel electronics inside a deep N-well can be implemented. The high voltage ( $\sim 50$  V) leads to a small depletion zone with fast charge collection. Most of the substrate is passive and the wafer can be thinned to  $< 50 \mu\text{m}$ .
